Voice Confirmation: Data Flow

End-to-end flow

What happens at each handoff

1. **An order is pending.** It is entered in Ordely or imported, then stored with its shop and customer/order details.
2. **Ordely selects an attempt.** The call orchestrator checks the order state, shop call window, retry eligibility, and whether the voice agent has capacity. It creates or selects the call-attempt record and dispatches the task.
3. **The voice runtime starts a simulated call.** It registers with Ringio and requests a simulated destination. Ringio routes the attempt to an available registered app; the destination is not dialed through a carrier.
4. **The app and agent negotiate media.** They exchange WebRTC offer/answer descriptions and ICE candidates through Socket.IO. After a connection is selected, audio travels over WebRTC directly between the app and agent runtime, not through the signaling server.
5. **The agent speaks and listens.** The runtime bridges the app's audio to Gemini Live and sends generated speech back to the app. It captures call lifecycle events and conversation data.
6. **The runtime reports back to Ordely.** Authenticated callbacks associate events and the final structured result with the dispatched task. Transcripts and audio artifacts are handled separately from the live audio stream.
7. **Ordely decides what the result means.** Backend policy checks the reported intent and confidence and confirms the order is still pending before applying a change. A completed call is not automatically a confirmed order.
8. **The merchant sees the outcome.** Ordely updates call/order views and may publish a configured order-status webhook to the connected platform.

Outcome handling

- A clear, sufficiently confident confirmation or decline can update a still-pending order.
- Ambiguous or low-confidence intent is not treated as confirmation; it can be retried or reviewed by staff.
- No answer and technical failures are recorded as call outcomes and follow the bounded retry policy. After the final eligible attempt, unresolved orders can be marked unreachable for staff follow-up.
- If a merchant or another process already changed the order, the callback must not overwrite that decision.

The confidence threshold defaults to `0.7`; the current maximum is three attempts. Configuration and policy are enforced by Ordely's backend, not by the agent's spoken response.

Notification boundary

There are three different things that can be called a notification:

- **Merchant dashboard update:** call and order status changes are reflected in Ordely for the shop user.
- **Connected-platform webhook:** an enabled integration can receive an `order.confirmed` or `order.cancelled` event.
- **Direct message to the buyer:** no post-call SMS, WhatsApp, or email was found in the current flow. This would need its own channel, consent rules, templates, and delivery tracking.

Current versus not included

Current: simulated Ringio call to a registered app, Gemini Live conversation, backend callbacks and policy checks, call/order persistence, and configured merchant/platform status updates.

Not included in this simulation: customer PSTN/SIM dialing, a configured TURN media relay, and direct buyer notifications after the call.
